

Structural Change in Global Value Chains

Hang Hu

University of Melbourne

Preliminary
October 8, 2018

World Input-Output Table

- ▶ S sectors in J countries
- ▶ Row: sell intermediate input (I.I) to country-sector; sell final good to countries.
- ▶ Column: buy I.I from country-sector; make value added (VA) from primary factor
- ▶ Global Value Chains (GVC): the value of all activities such as sourcing of I.I and primary factor, that are directly and indirectly needed to produce final goods.

		Input use & value added								Final use			Total use
		Country 1				Country J				Country 1	...	Country J	
Inputs Supplied	Country 1	Sector 1	X_{11}^{11}	...	Sector S	...	Sector 1	...	Sector S	F_{11}^1	...	F_{1j}^1	GO_1^1
		X_{11}^{1s}	X_{1j}^{1s}
		Sector S	X_{11}^{s1}	...	X_{11}^{ss}	...	X_{1j}^{s1}	...	X_{1j}^{ss}	F_{11}^s	...	F_{1j}^s	GO_1^s
	X_{ij}^{1s}	F_{ij}^1	GO_j^1
	Country J	Sector 1	X_{j1}^{11}	...	X_{j1}^{1s}	...	X_{jj}^{11}	...	X_{jj}^{1s}	F_{j1}^1	...	F_{jj}^1	GO_j^1
		X_{j1}^{1s}	X_{jj}^{1s}
		Sector S	X_{j1}^{s1}	...	X_{j1}^{ss}	...	X_{jj}^{s1}	...	X_{jj}^{ss}	F_{j1}^s	...	F_{jj}^s	GO_j^s
Value added		VA_1^1	...	VA_1^s	VA_j^1	VA_j^s	...	VA_j^s	F_{j1}^1	...	F_{jj}^s	GO_j^s	
Gross output		GO_1^1	...	GO_1^s	GO_j^1	GO_j^s	...	GO_j^s					

Motivation

Definition

Let B denotes the global input-output matrix: $b_{ij}^{rs} = \frac{X_{ij}^{rs}}{GO_j^s}$, the vector of sectoral centrality E is defined as

$$E = (I - B)^{-1} \mathbb{1}$$

- ▶ In chapter 2, this centrality is called supply multiplier.
- ▶ In network, this is Bonacich centrality. Here it is a measure of direct and indirect supply connection from this sector to all other sectors.

Motivated Question

Chapter 2 suggests an important role of domestic centrality in structural change. Does this global centrality matters for structural change?

Fact

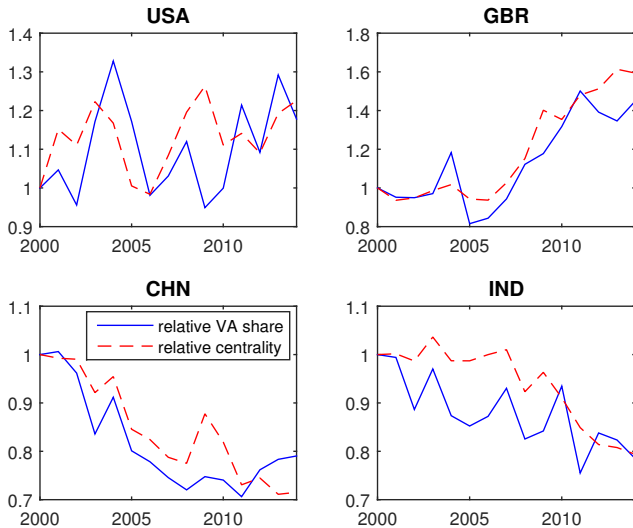

Figure: Crop and animal production, hunting and related service activities

Fact

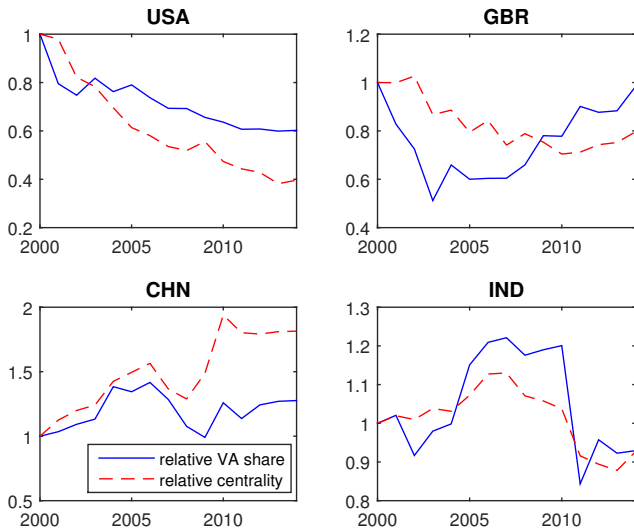

Figure: Manufacture of computer, electronic and optical products

Fact

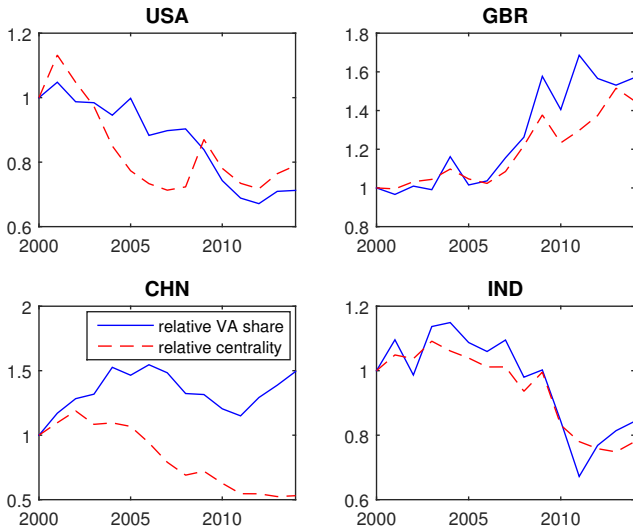

Figure: Telecommunications

Question

Question 1

How does trade of I.I and final output affect structural change?

- ▶ Domestic VA share based structural change
- ▶ Accounting mechanism
- ▶ Multi-country, multi-sector and multi-stage trade model

Question 2

If trade matters, which type of trade?

- ▶ International I.I trade vs. international final output trade
- ▶ International I.I trade vs. domestic I.I trade

Mechanism

Accounting Entity in GVC

In the supply side, trade flow is

$$P_i^r Q_i^r = \sum_{s=1}^S \sum_{j=1}^J b_{ij}^{rs} P_j^s Q_j^s + P_i^{rC} C_i^r$$
$$\gamma_i^r \equiv \frac{P_i^r Q_i^r}{GDP} = \sum_{s=1}^S \sum_{j=1}^J b_{ij}^{rs} \frac{P_j^s Q_j^s}{GDP} + \frac{P_i^{rC} C_i^r}{GDP}$$

- ▶ GDP is world GDP
- ▶ γ_i^r is Domar weight in terms of world GDP

Domar weight vector is solved as following:

$$\gamma = (I - B)^{-1} \lambda \tag{1}$$

- ▶ λ is vector of consumption share in terms of world GDP

Structural Term

VA share is constructed by

$$\begin{aligned}\eta_i^r &= \frac{VA_i^r}{VA_i} \\ &= \frac{VA_i^r}{GO_i^r} \frac{GO_i^r}{GDP} \frac{GDP}{VA_i} \\ &= (1 - \sigma_i^r) \gamma_i^r \frac{GDP}{VA_i}\end{aligned}$$

► $\sigma_i^r = \sum_{t=1}^S \sum_{k=1}^J b_{ki}^{tr}$

Relative VA share is given by

$$\frac{\eta_i^r}{\eta_i^s} = \frac{1 - \sigma_i^r}{1 - \sigma_i^s} \frac{\gamma_i^r}{\gamma_i^s} \quad (2)$$

Empirical Evidence

Data

The latest World Input-Output Database contains

- ▶ $J = 44$ countries (43 major economies + rest of world)
- ▶ $S = 56$ sectors: 2-digit ISIC revision 4 level
- ▶ $T = 15$ years: 2000-2014

Perfect database to study effect of trade on structural change

- ▶ At any year, we have $44 \times 56 = 2464$ nodes, a big trade network.
- ▶ At any sector, we have country year panel $J \times T$.
- ▶ At any country, we have sector year panel $S \times T$.

Balanced dataset contains 30 sectors.

Country Year Panel

At every sector, we run the following regression

$$\hat{\eta}_{it} = \alpha + \beta \hat{e}_{it} + \hat{x}'\tau + f_i + f_t + u_{it}$$

- ▶ $\hat{\eta}_{it}$ is VA share relative to the benchmark sector.
- ▶ \hat{e}_{it} is centrality relative to the benchmark sector.
- ▶ Benchmark sector: manufacture of chemicals and chemical products.
- ▶ \hat{x} are control variables: Upstreamness and downstreamness (Antras and Chor 2018).

Result

- ▶ Centrality: Positive and significant at 1 percent for all 29 sectors.
- ▶ Upstream and downstream sectors tend to lose VA share, but the relationships are not as robust as in centrality.

Sector Year Panel

At every country, we run the following regression

$$\hat{\eta}_t^r = \alpha + \beta \hat{e}_t^r + \hat{x}' \tau + f_r + f_t + u_{rt}$$

- ▶ The panel here is sector, otherwise same as the last slide.

Result

- ▶ Centrality: Positive and significant at 1 percent for 40 out of 44 countries.
- ▶ Upstream and downstream sectors tend to lose VA share, but the relationships are not as robust as in centrality.

One Stage Model

Model Setup

- ▶ This model follows Lorenzo and Parro (2015); and Antras and Chor (2018).
- ▶ J countries: i and j denote country
- ▶ ij in subscript: international trade from i to j
- ▶ S sectors: r and s denote sector
- ▶ rs in superscript: inter-sectoral trade from r to s
- ▶ Continuum of firms: $\omega^r \in [0, 1]$; for every $r=1, \dots, S$.
- ▶ For intermediate good, trade costs are sector pair specific.
- ▶ For final good, trade costs are sector specific.
- ▶ All markets are competitive.

Preference

Utility of representative consumer is Cobb-Douglas sum of sectoral consumption

$$u(C_j) = \prod_{s=1}^S (C_j^s)^{\varepsilon_j^s} \quad (3)$$

- ▶ For any country j : $\sum_{s=1}^S \varepsilon_j^s = 1$

Firm Level Production

Constant return to scale Cobb-Douglas function

$$y_j^s(\omega^s) = z_j^s(\omega^s)(l_j^s(\omega^s))^{1-\sum_{r=1}^S \beta_j^{rs}} \prod_{r=1}^S (M_j^{rs}(\omega^s))^{\beta_j^{rs}} \quad (4)$$

- ▶ Sector pair specific intermediate input
- ▶ Assume $z_j^s(\omega^s)$ is an i.i.d draw from Fréchet distribution:
 $\exp\{-T_j^s z^{-\theta^s}\}$
- ▶ Marginal cost: $c_j^s = Y_j^s w_j^{1-\sum_{r=1}^S \beta_j^{rs}} \prod_{r=1}^S (P_j^{rs})^{\beta_j^{rs}}$
- ▶ Price: $P_j^s(\omega^s) = \frac{c_j^s}{z_j^s(\omega^s)}$

Intermediate Input Demand

Buy sector pair specific intermediate input from the lowest price producer

$$P_j^{rs}(\omega^r) = \min_i \left\{ \frac{c_i^r \tau_{ij}^{rs}}{z_i^r(\omega^r)} \right\}$$

Sector pair intermediate input

$$M_j^{rs} = \left(\int_0^1 q_j^{rs}(\omega^r)^{\frac{\sigma^r-1}{\sigma^r}} d\omega^r \right)^{\frac{\sigma^r}{\sigma^r-1}}$$

Final Good Demand

Buy sector specific final good from the lowest price producer

$$P_j^{rF}(\omega^r) = \min_i \left\{ \frac{c_i^r \tau_{ij}^{rF}}{z_i^r(\omega^r)} \right\}$$

Sector final good

$$C_j^r = \left(\int_0^1 q_j^{rF}(\omega^r)^{\frac{\sigma^r-1}{\sigma^r}} d\omega^r \right)^{\frac{\sigma^r}{\sigma^r-1}}$$

Key Equations Following Eaton and Kortum (2002)

Expenditure Share

$$\pi_{ij}^{rs} = \frac{T_i^r (c_i^r \tau_{ij}^{rs})^{-\theta^r}}{\sum_{k=1}^J T_k^r (c_k^r \tau_{kj}^{rs})^{-\theta^r}} \quad (5)$$

$$\pi_{ij}^{rF} = \frac{T_i^r (c_i^r \tau_{ij}^{rF})^{-\theta^r}}{\sum_{k=1}^J T_k^r (c_k^r \tau_{kj}^{rF})^{-\theta^r}} \quad (6)$$

Price

$$P_j^{rs} = A^r \left(\sum_{k=1}^J T_k^r (c_k^r \tau_{kj}^{rs})^{-\theta^r} \right)^{-\frac{1}{\theta^r}} \quad (7)$$

$$P_j^{rF} = A^r \left(\sum_{k=1}^J T_k^r (c_k^r \tau_{kj}^{rF})^{-\theta^r} \right)^{-\frac{1}{\theta^r}} \quad (8)$$

Multiple Stage Model

Why Multiple Stage Matters?

1. Multiple stage emphasize the fact of vertical specialized production.
 - ▶ iphone: design & processor in Apple \implies display & memory in Toshiba and Samsung \implies assembling & test in Foxconn
2. This vertical fragmentation deepens over time (Hummels et al. 2001).
3. Global vertical fragmentation heterogeneously distribute VA across countries and across sectors (Timmer et al. 2014).
 - ▶ Countries and sectors are in different position of GVC.
 - ▶ iphone: US (50%); Japan and Korea (20%); China (2%) approx.
 - ▶ Their position change over time.
4. Multiple stage has different implication on trade elasticity.
 - ▶ Multiple stage production implies I.I pass multiple borders.
 - ▶ Small reduction in tariff can generate large trade rise (Yi 2003).
 - ▶ In one stage model we need large tariff reduction or large elasticity.

Model Setup

- ▶ This model extends the one sector multiple stage model (Antras and de Gortari 2017) to multiple sector multiple stage model.
- ▶ J countries: i and j denote country; $\mathcal{J} = \{1, \dots, J\}$
- ▶ S sectors: r and s denote sector
- ▶ Continuum of firms: $\omega^r \in [0, 1]$; for every $r=1, \dots, S$.
- ▶ N production stages: n denotes stage; $l(n)$ denotes location at stage n ; $N + 1$ denotes final consumption
- ▶ rs in superscript: inter-sectoral trade from r to s
- ▶ $l(n - 1)l(n)$ in subscript: trade flow from $l(n - 1)$ to $l(n)$

Model Setup

- ▶ Every good takes N stages to produce.
- ▶ At stage 1, production uses labour and finished input from other sectors at the same country (**horizontal integration**).
- ▶ At stage $n > 1$, production combines labour, finished input, with unfinished good from stage $n-1$ (**horizontal integration + vertical integration**).
- ▶ At every stage, location choice is endogenous.
- ▶ When a good (finished or unfinished) crosses border, the sector and country pair specific trade cost (τ_{ij}^s) is incurred.
- ▶ All markets are competitive.

Technology

Firm level price relation

$$P_{l(n)}^s(\omega^s) = \left(\frac{c_{l(n)}^s}{z_{l(n)}^s(\omega^s)} \right)^{\alpha_n} \left(P_{l(n-1)}^s(\omega^s) \tau_{l(n-1)l(n)}^s \right)^{1-\alpha_n} \quad (9)$$

- ▶ Horizontal marginal cost: $c_{l(n)}^s = Y_{l(n)}^s w_{l(n)}^{1-\sum_{r=1}^S} \prod_{r=1}^S \left(P_{l(n)}^r \right)^{\beta_{l(n)}^{rs}}$
- ▶ Vertical marginal cost conditional on endogenous location
- ▶ When $n = 1$, $P_{l(1)}^s(\omega^s) = \frac{c_{l(1)}^s}{z_{l(1)}^s(\omega^s)}$
- ▶ Final good price at j : $P_j^s(\omega^s) = P_{l(N)}^s(\omega^s) \tau_{l(N)j}^s$

Optimal Location Problem

Final good producer minimizes final good price by solving optimal production path $l_j^s(\omega^s) = \{l_{1j}^s(\omega^s), \dots, l_{Nj}^s(\omega^s)\}$.

$$l_j^s(\omega^s) = \arg \min_{l \in \mathcal{J}^N} \left\{ \prod_{n=1}^N \left(\frac{c_{l(n)}^s}{z_{l(n)}^s(\omega^s)} \right)^{\alpha_n \delta_n} \prod_{n=1}^{N-1} \left(\tau_{l(n)l(n+1)}^s \right)^{\delta_n} \tau_{l(N)j}^s \right\}$$

- ▶ $\delta_n \equiv \prod_{m=n+1}^N (1 - \alpha_m)$
- ▶ Optimal path is determined by upstream and downstream marginal cost and efficiency (**vertical cost**); and other sectoral input cost at each stage (**horizontal cost**).

Eaton and Kortum (2002) Framework

Assume $\prod_{n=1}^N [z_{l(n)}^s(\omega^s)]^{\alpha_n \delta_n}$ is an i.i.d draw from Fréchet distribution:
 $\exp\{-\prod_{n=1}^N [T_{l(n)}^s]^{\alpha_n \delta_n} z^{-\theta^s}\}$.

- ▶ As suggested by Antras and de Gortari (2017), this is equivalent to assume under a decentralized approach, $[z_{l(n)}^s(\omega^s)]^{\alpha_n \delta_n}$ is an iid draw from Fréchet distribution: $\exp\{-[T_{l(n)}^s]^{\alpha_n \delta_n} z^{-\theta^s}\}$

Solution

Probability or expenditure share on a particular path ending in country j

$$\pi_{lj}^s = \frac{\prod_{n=1}^N \left([T_{l(n)}^s]^{\alpha_n} [(c_{l(n)}^s)^{\alpha_n} \tau_{l(n)l(n+1)}^s]^{-\theta} \right)^{\beta_n}}{\sum_{l \in \mathcal{J}^N} \prod_{n=1}^N \left([T_{l(n)}^s]^{\alpha_n} [(c_{l(n)}^s)^{\alpha_n} \tau_{l(n)l(n+1)}^s]^{-\theta} \right)^{\beta_n}} \quad (10)$$

- ▶ $l_{N+1} = j$
- ▶ If $N=1$, $\pi_{l(N)j}^s = \frac{T_{l(N)}^s [c_{l(N)}^s \tau_{l(N)j}^s]^{-\theta}}{\sum_{l \in \mathcal{J}} T_{l(N)}^s [c_{l(N)}^s \tau_{l(N)j}^s]^{-\theta}}$, consistent with one stage model.
- ▶ If only one sector, consistent with Antras and de Gortari (2017).
